Abstract

This study provides an in-depth analysis on school dropouts in Yemen through analyzing the raw data of three national official surveys; Household Budget Survey (HBS) 2005-2006, Child Labor Survey (CLS) 2010 and HBS 2014. In each survey, a number of dropouts' reasons was investigated and seven of them were found common in all three surveys. With attendance status (attended, not attended) as a dependent variable, the binary logistic regression was used to find out statistical significant reasons for school dropouts in Yemen in the two age groups 6-14 and 15-17 years. From each survey, some significant independent variables (reasons) were detected. These significant reasons were divided into six related dimensions namely; poverty, schools' situation, education willingness, orphanhood, sex of the children and residence areas. Careful consideration to these dimensions lead us to suggest a prototype that addresses the dropout problem and its root in Yemen.

Keywords

Out of School; Logistic Regression; Yemen

Introduction

The reports of HBS 2005-2006, CLS 2010 and HBS 2014 had mentioned 25.7%, 18.2% and 16.6% prevalence rates of not attending respectively [1-3], where the positive progress is clear. However, very recently UNICEF 2018 had estimated the number of children and adolescents who are in the school ages and out of schools by 2,000,000 [4,5]. Taking into account, the total projected population of children and adolescents aged 6-17 years to be 8220000 [6], it is easy to estimate the new out of school

prevalence rate as 24.3%. This relapse is mainly due to the ongoing war that erupted on March 2015 and still storming the whole country and considered one of the big motives for us to conduct this research. Among the Middle East and North Africa (MENA) countries, Yemen has one of the largest number of children out of school [7,8]. National Social Protection Monitoring Survey (NSPMS) reveals that during the 2012/2013 school year there were around 1.6 million girls and boys aged 6-14 years that were not enrolled in the education system, that is more than a quarter (27.5%) of the primary and lower secondary age population is out of school [9]. After three years of brutal war in Yemen, the education system is on the brink of a total collapse as nearly 2 million children-more than a quarter of all school-aged children- are not enrolled during the 2016/2017 school year [4]. One of the major bleak implication of this war is that all public schools' teachers left without salaries for around a year [5]. UNICEF March 2018, is reporting horrific figures about the schooling situation; 2500 schools are out of use, 66% of schools were damaged, 27% of schools have closed down and 7% of the left schools are used as shelters for displaced families or for military purposes [5].

Student attendance serves as an effective predictor of future academic achievement as well as of high school graduation [10]. Improving access to schooling surely depends on reducing children drop out. Hunt (2008), argued- in his review- that many factors associated with drop out that lie at the individual, household, school and community level. Moreover, he had come to conclude that drop out is the result of a process rather than a single event, has more than one proximate cause and is fairly irreversible [11]. Yet identifying the causes of dropping out is extremely difficult. The act of dropping out is influenced by an array of factors related to both the individual student and to the family, school, work-related reasons and community settings in which the student lives [12-14]. If many factors contribute to this phenomenon over a long period of time, it is virtually impossible to demonstrate a causal connection between any single factor and the decision to quit school [14]. Some scholars have viewed dropping out of school as the final stage in a dynamic and cumulative process of disengagement [15,16] or withdrawal

from school that is influenced by a variety of proximal and distal factors [17]. Exclusion from the formal educational system has long term implications for the country's social and economic development. At the individual level, literatures showed that low investments in education are strongly associated with higher levels of violence, precarious health, early pregnancy, low productivity and lower earnings [18-20].

Understanding factors that constrain children's school enrollment, is the corner stone for any successful intervention. Various studies have identified a number of factors that constrain children's school enrollment. For example, Filmer (1999) documented a positive significant relationship between school attendance and household level of wealth for 41 developing countries using DHS data [21]. In Egypt, children of poor families tend to be dropped out of school [22] and there is significantly positive association between household level of wealth and child's schooling [23,24].

The aims of the present research are:

- To explore the trend of enrollment of the Yemeni children at school age.
- To better understand factors that negatively affecting the Yemeni children enrollment.

Data Source

This research intends to use and compare data of three Yemeni national surveys in a period covers a span 10 year. More precisely, we intend to use the raw data of HBS 2005-2006, the CLS 2010 and the HBS 2014. The key question in the three surveys was Is the child is currently attending school. Each survey had compiled, then, several reasons for not attending. Some reasons were common in the three surveys and others were different. After separating children and adolescents 6-17 years from the raw data of the three surveys, the sample sizes were 10107 of the HBS 2005-2006, 9614 of the CLS 2010 and 21587 of the HBS 2014, among them 2596, 1745 and 3585 children and adolescents were found out-of-school in these surveys respectively.

Analysis and Results

The schooling system in Yemen has two levels. Basic education level that constitutes nine grades for children aged 6-14 and the Secondary level that constitutes three grades for adolescents aged 15-17 inclusive. So, our analysis will be done on these two levels separately.

In this research, our focus will be on children and adolescents who were out-of-school at the surveys time and ignore their schooling history prior to them.

Table 1, is listing seventeen reasons for not enrolling in schools. Six reasons are common in the three surveys; namely No school, Family not interested, Work for someone, Work for family, Illness and Too young. Too young is the main reason in both CLS 2010 and HBS 2014 for the age group 6-14 years. Family not interested comes as the next important factor specially for female students. Illness of male students in the age group 15-17 of both CLS 2010 and HBS 2014 is another important factor and also questionable. No schools available in the dropouts' areas and also their inability to afford the schooling costs are also major concerns. No female teachers seem to contribute negatively to the process of enrollment. It is very clear that most of the dropouts are of the rural areas in the three surveys. This result is very crucial as it reflects major social discrepancies between urban and rural areas in Yemen. Orphans are less likely to enroll. In HBS 2005-2006; enrolled poor students were less than the non-poor students of HBS 2014.

Table 1: Proportions of out-of-school children and adolescents by reason of not enrolling.

Reasons for not being enrolled in school		HBS 2005-2006				CLS 2010				HBS 2014			
		6-14		15-17		6-14		15-17		6-14		15-17	
		F	M	F	M	F	M	F	M	F	M	F	M

F: Female, M: Male

Further statistical analyses are shown on Tables 2, 3 and 4, with one exception that the analysis here is done on the whole dropout samples rather than age groups. This is duly because no substantial differences were found for each age group separately. When area was compared with the reasons of not attendance, Table 2 was produced. In HBS 2005-2006, 37.8% and 23.1% of the surveyed households were not interested to enroll their children in both areas. However, these figures have changed dramatically in the subsequent surveys more specifically in CLS 2010. The same story is clear with the child's attitude to enroll. It is important to notice that the schooling circumstances (No schools, Hard to reach schools, No female teachers) in the rural areas are much worse than urban areas. This result suggests a fair revision to the schooling distribution in Yemen through a strategic plan. Too young is a weird reason for not attending specially in both CLS 2010 and HBS 2014. It is also unexpected to find the percentage of Too young reason in urban areas to exceed the percentage of the rural areas.

Table 2: Area by reasons of not attending schools for the age group 6-17 years.

Reasons for not being enrolled in school	HBS 2005/2006		CLS 2010		HBS 2014	
	Urban	Rural	Urban	Rural	Urban	Rural
No schools	1.2	13.5	1.6	14.1	0.3	8.9
Hard to reach	1.9	12.2			0.2	5.5
Child not interested	36.6	16.2	5.4	6.0		
Family not interested	37.8	23.1	2.8	7.4	9.6	12.4

Other reasons	7.7	3.3	0.1	1.0	2.8	2.0
Sample size	725	1871	669	976	1612	1973

As shown on Table 1, HBS 2005-2006, CLS 2010 and HBS 2014 have included data on poverty. So, in Table 3, we compare the poverty status of households with the reasons their children not attending schools. Three factors take the lead as main reasons for not attending. These factors are family not interested, child not interested and no female teachers respectively for the HBS 2005-2006. Too young factor in the HBS 2014 seems unrealistic and hiding something inexpressible by households (HHs). In HBS 2005-2006, the percentage of poor children and adolescents (by virtue, households) was less than the rich. This percentage was reversed in HBS 2014 where the poor has increased by about 10 percent. In general, this table shows that poor children and adolescents are more vulnerable to be out of school than the rich.

Table 3: Poverty by reasons of not attending school for the age group 6-17 years.

Reasons for not being enrolled in school	HBS 2006	2005-2006	CLS 2010		HBS 2014	
	Non-poor	Poor	Non-poor	Poor	Non-poor	Poor
No schools	9.8	10.4	9.6	0.0	2.0	8.0
Hard to reach	7.7	11.2			2.1	4.3
Child not interested	24.3	19.2	6.1	0.0		
Family not interested	27.2	27.2	5.9	0.0	9.7	13.6
Work for someone	0.4	0.6	0.1	0.0	0.1	0.3
Work for family	9.3	7.7	0.3	0.0	1.0	1.4
No teachers	0.9	1.0			0.1	2.6
No female teachers	15.0	16.4			1.2	4.1

Pregnancy	0.1	0.0				
Lack of sanitary	0.0	0.0			0.0	0.0
Too young	1.2	1.0	66.7	0.0	76.0	58.4
School isn't safe			1.2	0.0	0.4	0.2
Education isn't valuable			1.3	0.0		
To help in the household tasks			1.4	0.0		
Other reasons	3.8	5.4	0.7	0.0	2.4	2.7
Sample size	1382	1214	1552	118	1469	1898
%	53.2	46.8	92.9	7.1	43.6	56.4

Finally, when area was compared with the poverty status of the dropouts, it was found that the poor are more concentrated on the rural than urban areas (Table 4). Again, this result gives an indication of the deep gap between urban and rural areas in Yemen in education attainments.

Table 4: Area by poverty.

Poverty	HBS 2005-2006		CLS 2010		HBS 2014	
	Urban	Rural	Urban	Rural	Urban	Rural
Non-poor	40.8	59.2	41.3	58.7	62.5	37.5
Poor	25.2	74.8	33.9	66.1	32.5	67.5
Total	1320	2557	681	989	1619	1979

When the dependent variable is binary and the independent variables are categorical, the logistic regression model is appropriate method to study the relationship among the variables. Data analysis was done by logistic regression to assess the effect of each variable on the enrollment status through Backward Stepwise (Wald) method using SPSS 21.

The logistic regression model describes the relationship between a dichotomous response variable Y , coded to take the values 1 or 0 for success and failure, respectively, i.e.

$$p(x) = y = \frac{1}{1 + \exp(-\beta_0 - \beta_1 x)}$$

where $p(x)$ denotes the probability of success when the explanatory variable has the value x .

The two parameters β_0 and β_1 determine the location, slope and spread of the curve. And

$$\text{logit}(y) = \log\left(\frac{y}{(1-y)}\right)$$

$$\text{logit}(p(x)) = \log\left(\frac{p(x)}{1-p(x)}\right) = \beta_0 + \beta_1 x$$

The ratio $p(x)/(1-p(x))$ in above equation is the ratio between the probability of success and the probability of failure. That is, it is the odds of success! Hence, $\text{logit}(p(x))$ is the logarithm of the odds of success—called the log odds of success, given the value of x the explanatory variable [25].

Again, two separate logistic regression analyses of the two age groups will be performed to study the relationship between enrollment and all factors listed on Table 1.

In HBS 2005-2006 except illness, pregnancy and lack of sanitation, all other factors are interacting significantly with school attendance (Table 5). In CLS 2010, six factors are associating significantly with school attendance among them illness, poverty and unwillingness of children to be enrolled. No female teachers, poverty, sex of child and area are the most important factors in the HBS 2014. Further, it can be seen that male children are still having more chance to be enrolled than female.

Table 5: Logistic regression of reasons without-of-school for age group 6-14 years.

-Notsignificant

For the age group 15-17, no schools and hard to reach the available schools still important reasons in HBS 2005-2006 for not attending (Table 6). Promoting children and families to understand the crucial importance of education seems a top priority for decision makers. The analysis showed three main factors to be common in the three surveys; sex in favor of male children, area in favor of urban areas and poverty. It should be noted that in the presence of other reasons, no specific meaning for the constant in the regression analyses.

Table 6: Logistic regression of reasons without-of-school for age group 15-17 years.

Discussion

Hunt (2008) stated pupils' dropout reason does not consist of only one but several reasons [11]. The case here seems no different but the hard part is to understand how the reasons are connected. In other words, no matter how many reasons but how one or several reasons strongly impacting and stimulating the dropout problem.

Looking at the reasons used in the three surveys and the refined reasons emerged by the logistic regression analysis, it is easy to distribute these reasons into four main categories; school related reasons, family-related reasons, work-related reasons and situation related reasons. The first three categories were discussed before [12,13,26], but in the Yemen context, situation is so harsh more specifically in the rural areas. This harsh situation made it difficult to build and establish enough schools in all regions that made thousands of students unable to reach the available ones.

In this study, we only dealing with children and adolescents who are not attending schools at the time of surveys. In other meaning, we have no idea whether the investigated children and adolescents had some schooling years on the past or not. Therefore, the present research is focusing on studying the present situation away from any other probable factors that may influence the dropout process.

In some countries, reasons of pupils' dropout are including overcrowded classrooms, the amount of schooling hours, pedagogical, missed too many school days, poor grades/failing, did not like school and could not keep up with school work and didactic skills [11,13,27,28], in Yemen-unfortunately- we still have problems in providing schools and teachers. Building more schools and providing transportation or offering some kind of compensation for those who live far away from schools, should be a priority at the educational planners to tackle the problem of school absence and reaching schools. When there is no schools or teachers, children and adolescents are automatically out of education. However, no female teachers are another issue as it is

an indication that in some areas norms are still prohibiting female students to be educated by male teachers. This problem is central in the female education context in Yemen and lots of efforts and patience should be devoted to break these bad norms before moving forward. A suggested solution to tackle this problem is to give distinctive financial assistances and incentives to female teachers to settle down in the rural areas.

Four major factors were determined by Cook and Ezenne (2010) that influencing students' absenteeism in primary schools in Jamaica [29]. These factors are parental, student, community and school related issues. Each factor was further divided into subfactors. These subfactors are including financial constraints (poverty) of parents, sickness of students and poor transportation to schools. Attendance is a particular concern for low-income students, as they may have more barriers to attending school and research on attendance across the U.S. indicates that higher rates of absenteeism are associated with higher levels of poverty [10]. Furthermore, other studies considered poverty as the main reason of students' absenteeism [30-32].

The associations between poverty, willingness to education and health are overlapping. For instance, if the family is poor, there is a greater risk that its members will get ill. Likewise, in the case of illness, the household economy will be affected negatively by medical costs and absence from work. The act of dropping out is influenced by an array of factors related to both the individual student and to the family, school and community-settings in which the students live. In line with other studies [33,34], this study has proved a significant association between illness and school attendance. In fact, illness could affect the schooling of children and adolescents either directly by long-and-short-term absence or in their achievement. In line with many scholars, we believe that dropout of schools is only the final stage of dynamic and cumulative process that is influenced by a variety of proximal and distal factors [15-17,35]. Moreover, illness could lead to parents' mortality (orphanhood) and this could lead children or adolescents to stop education and work for someone (males) or work for the family (males + females) or to

help in the household tasks (females). Orphanhood could also lead families or children to be not interested in education.

Conclusion and Recommendations

Looking at the data analysis results from the three surveys, leads -broadly- to consider six main dimensions affecting the school attendance in Yemen. These dimensions are poverty status of HHs, schools' situation, education interest (willingness), orphanhood, sex of children and adolescent and residence area. Each dimension constitutes some factors as follows:

Poverty	Schools situation	Willingness	Orphanhood	Sex child	Area
Work for someone	No schools	Child not interested	Mother died	Male	Urban
Work for family	Hard to reach	Family not interested	Father died	Female	Rural
Illness	No teachers	Child is too young			
Help in the HH tasks	No female teachers	Education isn't valuable			
	School not safe				

Accordingly, the following prototype or model is suggested, to address the dropout of schools' phenomenon in Yemen:

The prototype states that deep and long poverty situation at the HHs, leads definitely to both illness and loss of interest in education at the families and children. Illness could lead to children orphanhood and also to loss of interest education either families or children. Orphanhood could leads children to work for someone (males), work for the family (males + females) and help in household tasks (females). Education interest can be negatively affected by non-availability of schools, teachers and female teachers. Moreover, factors such as the long distances to schools, safety of schools, the impression that is not valuable education and too young are also important of losing interest in education. Some of these factors are more likely to occur on the rural areas of Yemen.

So, any future planning to reduce the dropout in schools should take into consideration that alleviating poverty of the Yemeni people, improving the schooling distribution and conditions, stopping the war-to make schools safe- and increasing the awareness of the education importance, are together the only possible road map.
