Abstract

The economic charges and health implications of food spoilage and food waste handling are increasing. Contamination of food sources by different sources of contaminants remains a major public health concern. In the last decades, researches have focused on developing safer natural products and innovations to meet consumers' acceptance as alternatives to synthetic food preservatives. Many recent novel preservative techniques and applications of both natural and synthetic origin continue to proliferate in food and chemical industries. In particular, some essential oils of plant origin are potent food preservatives and are thus attractive alternatives to synthetic preservatives. For the reasons mentioned above, this studied aimed evaluate the chemical composition, antioxidant, antibacterial and antifungal properties of the essential oil obtained from the *Cymbopogon citratus* of Angolan origin. Its major constituents analyzed by GC-MS were α-citral (40.55%), β-citral (28.26%), myrcene (10.50%) and geraniol (3.37%). The essential oil antioxidant capacity was statistically identical to that of synthetic antioxidants (DPPH IC\(_{50}\) of 41.7 μg/ml) and superior to that of extracts obtained from fresh leaves of the plant (DPPH IC50 of 55.7 μg/ml). The oil also demonstrated high antibacterial activity even against multidrug resistant strains of *Staphylococcus aureus, Staphylococcus epidermidis, Escherichia coli* and *Klebsiella pneumoniae* and antifungal activity against *Candida albicans* and Non-*Candida albicans, Candida parapsilosis* and *Candida tropicalis*. 
Keywords

Introduction

The use of essential oils (EOs) as additives in order to simultaneously tackle two issues related with food preservation, oxidation and microbial contamination, is an approach that gained adherents in recent years [1]. This resulted from the realization that these natural products appeared to bring together the desired characteristics for that purpose, including, atoxicity at low concentrations, antioxidant activity, i.e. the ability to inhibit the process of food oxidation, antimicrobial properties and biodegradability. Hence it is not surprising the active research that is being conducted on the subject in order to uncover the properties of the thousands of EOs available [2,3]. In fact, the use of natural antimicrobial food preservatives (biopreservation) could ensure the safety and quality of food being an alternative to other systems of preservation such as chemical or thermal ones. Obviously, the higher the antioxidant activity demonstrated and the greater the spectrum of activity of the EO, the better will be its performance as preservative. It is also desirable that the addition of oil does not change the organoleptic characteristics of the food. Interesting results have already been reported with EOs from several plants [4-8]. This research describes the experimental work done on the EO of *Cymbopogon citratus*
(lemongrass) of Angolan origin. The EO of *C. citratus* is already in use by the pharmaceutical industry as a source of new phytochemical molecules for the development of new drugs. Previous studies on the leaf EO of *C. citratus* revealed, antityrosinase and antioxidant activities in human cells [9], anti-inflammatory in rats [10], anti-carcinogenic effects and cholesterol reduction in mice [11,12]. Furthermore, many studies have reported the antimicrobial activity of lemongrass oil originating from different parts of the globe against a diverse range of microorganisms comprising Gram positive and Gram negative bacteria, yeast and fungi namely *Bacillus cereus, Bacillus subtilis, Escherichia coli, Klebsiella pneumoniae* [13], *Salmonella choleraesuis, Pseudomonas aeruginosa, Staphylococcus aureus* [14] and *Aspergillus flavus, Aspergillus fumigatus, Aspergillus niger, Alternaria alternata, Penicillium citrinum, Curvularia lunata* and *Trichoderma harzianum* [15]. In this particular work the main objective was to evaluate the antimicrobial activity of the *cymbopogon citratus* on multidrug resistant strains of *Staphylococcus* (aureus and epidermidis), *Escherichia coli, Klebsiella pneumoniae* and fungi (Candida albicans, tropicalis and parapsilosis). All these microorganisms may be food-borne and by this route represent a severe public health problem in large scale [16]. Food-borne diseases caused by bacteria and yeast are of major concern worldwide even in developed countries were up to 30% of the population have been reported to suffer from them every year. The severity of the problem might become more pronounced due to the proliferation of antibiotic-resistant strains [17]. Among the predominant bacteria involved in food-borne diseases, *Staphylococcus aureus* is a leading cause of gastroenteritis resulting from the consumption of a food in which enterotoxigenic *staphylococci* have grown and produced toxins. These are considered a potential biological threat because of their stability at high temperatures (100°C for 1 h). While not regarded as highly lethal agents due to the low mortality associated with the illness, *staphylococcal* enterotoxins can incapacitate individuals for two weeks [18]. Moreover it is predictable that *S. aureus* will continue to develop new virulence characteristics and new patterns of synthetic antibiotic resistance [19,20]. A similar drug resistance phenomenon is supposedly occurring with *S.
Epidermidis [21]. E. coli is reported to cause bloody diarrhea and can sometimes cause kidney failure and even death. K. pneumoniae is second only to E. coli as a urinary tract pathogen and cases of enteroinvasive Klebsiella pneumoniae and Escherichia coli sepsis from contaminated hamburgers are documented [22,23]. As in the case of bacteria previously mentioned, Klebsiella infections are encountered far more often now than in the past probably due to the emergence of increasingly resistant strains [24]. Apart from bacteria, fungal contamination of food is practically inevitable. Candida as many other yeasts and molds is undesirable in many foods manly due to its food spoiling activity, nevertheless, dangerous levels of Candida have been found in yoghurt [25]. Candida spp. is responsible for the most prevalent opportunistic fungal infections in humans and of particular significance in immune compromised individuals [26-28]. Additionally, and as this is an important characteristic for a food preservative, the antioxidant capacity of the Angolan Cymbopogon citratus EO was evaluated and compared with that of synthetic antioxidants. The use of natural substances to replace the synthetic antioxidants in food and pharmaceutical industries and in can result in important health benefits, since the latter have been associated with genotoxic and carcinogenic effects [29-33].

Material and Methods

Plant Source

The fresh aerial parts of C. citratus were obtained from a local market in Benguela, (latitude 12°58′ south; longitude 13°408′ east), Angola. The plants were identified by a taxonomist (Dr. Pedro Catarino Pires, ISPB, Benguela) and deposited in the Instituto Superior of Saúde de Benguela, ISPB, Benguela. The fresh plant sample was submitted to distillation (4 h) using a Clevenger apparatus to obtain the EO for further analysis. The procedure followed was that described in the European Pharmacopoeia [34]. The yield in EO was of 1.3%, corresponding, on average, to 1.5 ± 0.4 ml of EO per 111 g of fresh plant sample. A total of six samples of fresh plant, purchased in different days were used to obtain the six samples of EO. 2.2 Isolation, Characterization and Identification of
Constituents The EO was analyzed by GC-MS carried out in a Hewlett-Packard 6890 gas chromatograph fitted with a HP1 fused silica column, interfaced with an Hewlett-Packard mass selective detector 5973 (Agilent Technologies) operated by HP Enhanced Chem-Station software, version A.03.00. Components were identified by their retention indices on both SPB-1 and SupelcoWax-10 columns and from their mass spectra. Retention indices, calculated by linear interpolation relative to retention times of C8-C23 of n-alkanes, were compared with those of authentic standards included in our own laboratory database.

**Total Phenolic Content**

The amount of total phenolic compounds was determined in the aerial parts of *C. citratus* according to Jang et al. [35] using the Folin-Ciocalteu reagent. Each sample was extracted using methanol, for one hour. In brief, 2.5 g of a dried leaves sample was added to 100 ml of the solvent, under constant agitation for 1 hour. Afterwards, the solid was separated from the extract through vacuum filtration and a volume of 0.5 ml of each extract was added to 0.5 ml of Folin-Ciocalteu reagent. The mixture was left to rest for 3 min at room temperature before 1.0 ml of sodium carbonate 6% was added to it. After standing at room temperature for 120 min, absorbance readings were performed at 720 nm using a UV-Vis spectrophotometer (Beckman DU-64 spectrophotometer, Beckman Instruments Inc., Fullerton, CA). Total phenolics were quantified by means of a calibration curve obtained from measuring the absorbance of gallic acid standards. Results were expressed as milligrams of gallic acid equivalents per 100 g of fresh sample weight. 2.4 Antioxidant Activity The antioxidant activity of *C. citratus* EO was evaluated by measuring the bleaching of the purple-colored ethanolic solution of 2,2-diphenyl-1-picrylhydrazyl free radical (DPPH’). This methodology was performed using an ELX80 Microplate Reader (Bio-Tek) in the following way: the reaction mixture in each one of the 96-wells consisted of one of the different concentration of EO (20 μL) and 280 μL methanolic solution of DPPH radical (0.5 mM). After 30 minutes incubation, the changes in color (from deep-violet to light-yellow) were measured at 517 nm (Shimadzu, model UV-1800), according to the method
previously reported [36]. The butyl hydroxyl toluene (BHT) was used as a positive control while ethanol was the negative one. The percentage of inhibition (I%) of DPPH radical was computed through the equation:

$$I\% = \frac{A_{DPPH} - A_s}{A_{DPPH}} \times 100$$

where, As represents the absorbance of the solution of the sample extracts containing DPPH•, and ADPPH is the absorbance of the DPPH• solution. All determinations were performed in triplicate. The concentration of extract sample required for 50% inhibition of the DPPH free radical (IC\textsubscript{50}) was also calculated.

**Antibacterial Activity**

**Microorganisms**

The antimicrobial activity of *C. citratus* EO was evaluated using the following laboratory control strains: *Staphylococcus aureus* (ATCC 25923), *Staphylococcus epidermidis* (ATCC 12228), *Escherichia coli* (ATCC 25922), *Klebsiella pneumoniae* (ATCC 13883), *Candida albicans* (ATCC 10231), *Candida parapsilosis* (ATCC 2219) and *Candida tropicalis* (ATCC 750) and the antibiotic resistant strains isolated from Braga Hospital (Portugal, GPS:N 41º34′ W 8º24′): *Staphylococcus aureus* 1 (*S. aureus 1*); *Staphylococcus aureus* 2 (*S. aureus 2*); *Staphylococcus epidermidis* 1 (*S. epidermis 1*); *Staphylococcus epidermidis* 2 (*S. epidermis 2*); *Escherichia coli* 830 (*E. coli 830*); *Escherichia coli* 986 (*E. coli 986*); *Klebsiella pneumoniae* 822 (*K. pneumoniae 822*).

**Propagation and Maintenance of Microorganisms**

The studied microorganisms were streaked on the nutrient agar slants and then incubated overnight at (37±1 °C). The cultures were kept under refrigerated conditions and were sub-cultured every fifteen days. 2.5.3 In Vitro Testing Empty sterilized discs were impregnated with 5µl of oil diluted with DMSO to obtain different concentrations (5%, 10%, 20%, 40%, 60%, 80% and
100%). DMSO was used as negative control. The inoculated plates were incubated at 37°C for 24 or 48 hours for bacterial and fungal assessment, respectively. Antibacterial activity was evaluated by measuring the zone of inhibition in millimeters after the incubation period. All experiments were done in triplicate and the results are presented as mean±standard deviation of three independent experiments.

**In Vitro Antibacterial Activity:**

Antibacterial activity was determined by the disk diffusion method [37]. A positive control was done using the following antibiotics: methicillin (5 μg/disc); penicillin (10 μg/disc); amoxicillin/clavulanic acid (augmentim) (30 μg/disc); vancomycin (5 μg/disc) in Gram positive strains and ciprofloxacin (5 μg/disc), nitrofurantoin (300 μg/disc), ceftazidime (30 μg/disc); gentamicin (10 μg/disc) in Gram negative strains and a negative control was performed with DMSO for all tested strains. The antibacterial activity of all the tested antibiotics was interpreted according to the CLSI guidelines [38].

**In Vitro Antifungal Activity:**

Antifungal activity was also evaluated by the disk diffusion method in accordance to CLSI guidelines M44-A2. Candida spp. were tested in agar Miller Hinton (DIFCO) supplemented with 2% of glucose and 0.5 g/ml of methylene blue. Yeast suspension was adjusted to a final concentration between 1 and 5 x 10⁶ cells/ml and incubated at 35°C during 48 hours. The antifungal fluconazole, at a concentration of 5μg/disc, was the positive control to Candida spp. Results were interpreted according to CLSI guidelines [38].

**Statistical Analysis**

Data were reported as mean±standard deviation of nine measurements. Statistical analysis was performed using the statistical software package SPSS v 20.0 (SPSS for Windows; SPSS Inc., Chicago, IL). Mean comparison was made through an
independent sample t-test. Levene's test was utilized to assess the equality of variances. One-way ANOVA was used to compare three or more groups, and post-hoc Dunnett’s test was performed for simultaneous paired comparisons. P values less than 0.05 (95% confidence level) are reported as “statistically significant”.

**Results and Discussion**

The results of the chromatographic analysis of the *C. citratus* EO presented in Table 1 reveal that the chemical composition of *C. Citratus* EO obtained from plants grown in Angola is similar to that of plants from other provenances [5,39-41]. Accordingly, the major constituents are α-citral (40.55%), β-citral (28.26%), myrcene (10.50%) and geraniol (3.37%). The volatile fraction of *C. citratus* EO revealed the presence of 10 different compounds accounting for 83.86% of total peak area.

**Table 1:** Angolan *C. citratus* EO main components as revealed by GC-MS.

*Retention index relative to n-alkanes.

The preservation of food generally requires the use of various compounds to perform a range of functions namely antioxidants, antibacterial and antifungals. The ideal would be to find a single biopreservative that could perform all these functions simultaneously. In order to assess the antioxidant potential of the *C. citratus* EO, its free radical scavenging activity by the DPPH assay was measured (Figure 1).
Our results showed that no statistical significant differences exist between the free radical scavenging activities of the EO and butylated hydroxytoluene (BHT), a synthetic antioxidant applied in pharmaceutics and food products. The EO was able to reduce the stable free radical 2,2'-diphenyl-1-picrylhydrazyl to diphenylpicrylhydrazine with an IC$_{50}$ of 41.7 µg/ml, a value similar to that of the synthetic antioxidant (37.7 µg/ml). The leaves methanolic extract was found to be less efficient in radical scavenging with an IC$_{50}$ value of 55.7 µg/ml. This result suggests that when it comes to antioxidant compounds, the methanolic extract obtained from the leaves is not as rich as the oil. We attribute the high antioxidant activity manifested by the EO to the synergic action of the monoterpenoid compounds such as geranial, neral, and myrcene [42]. The chromatographic analysis (Table 1) reveals that these are abundant in the EO.

The antibacterial activity of the EO of the Angolan C. citratus is depicted in Figures 2 and 3.
Figure 2: Antibacterial activity of different EO concentrations of *C. citratus* against Gram positive ATCC and multidrug resistant strains. *Statistically different (95% significance) relatively to negative control DMSO.

It can be seen that hospital isolated *S. aureus* 1 and *S. aureus* 2 were sensitive to *C. citratus* EO at concentrations equal or superior to 60% while *S. aureus* ATCC 25923 growth was
inhibited at even lower concentrations (≥ 20%). *S. epidermidis* ATCC 12228 and the hospital isolated strains *S. epidermidis* 1 and *S. epidermidis* 2 had a similar pattern of sensitivity at EO concentrations equal or above 20%. These results are, in our view, relevant since they demonstrate the potential of the Angolan *C. citratus* EO as an antibacterial agent even against multidrug resistant strains. In order to better understand the effectiveness of the EO, the antibacterial activity of antibiotics in use against the strains studied was also evaluated. The results are summarized in Table 2.

**Table 2**: Antibiotic sensitivity pattern of multidrug resistant hospital isolated strains and their respective ATCC control strains.

Sensitivity values: R – Resistant; I – Intermediate; S – Sensitive. MET-Methicillin; P-Penicillin; AMC/AUG-Amoxicillin/Clavulamic acid; VA-Vancomycin (from CLSI guidelines).

Both hospitalar isolated strains of *S. aureus* presented an analogous pattern of resistance to methicillin, penicillin and amoxicillin-clavulamic acid, consistent with methicillin resistant profile. *S. aureus* (ATCC 25923) presented the expected sensitivity relatively to the tested antibiotics that usually have inhibitory effect on Gram positive bacteria (Table 2). *S. epidermidis* 1 was resistant to methicillin, penicillin and amoxicillin-clavulamic acid and vancomycin consistent also with the methicillin resistant profile. *S. epidermidis* 2 was sensitive to amoxicillin-clavulamic acid and resistant to penicillin, methicillin and vancomycin. By comparison, *S. epidermidis* ATCC 12228 was sensitive to all antibiotics tested for Gram positive bacteria.
Gram negative *E. coli* 830, *E. coli* 986 and *K. pneumoniae* 822 presented an intermediate resistance pattern, with growth inhibition at *C. citratus* EO concentrations equal or superior to 40% (Figure 3). In the case of *E. coli* 986 and *K. pneumoniae* the inhibition effect of the EO started at inferior concentrations (≥ 20%).

**Figure 2:** Antibacterial activity of different EO concentrations of *C. citratus* against Gram negative ATCC and multidrug resistant strains. *Statistically different (95% significance) relatively to negative control DMSO.*
The results thereby suggest that the oil is more effective on Gram positive bacteria. The higher resistance manifested by the Gram negative bacteria may be associated to the constitution of its outer membrane which acts as a relatively impermeable barrier [43]. Gram negative bacteria are inherently resistant to hydrophobic antibiotics, as their outer membrane limits the entry of these antibiotics into the cell [44]. Thus we can hypothesize that the *C. citratus* EO is less effective against Gram negative bacteria due to the same reason [24].

In the last decades, fungi have emerged as major causes of human disease, with invasive candidiasis (IC) as a leading cause of mycosis-associated mortality in developed countries [45]. *Candida albicans* (*C. albicans*) is the most frequent species isolated, but other Candida are of special concern, due to abnormal virulence and reduced susceptibility to antifungal agents. *C. parapsilosis* and *C. tropicalis* are the most prevalent NCAC species with a crescent number of infections [46,47]. The *C. citratus* EO showed effectiveness in inhibiting the growth of all yeast strains studied as shown in Figure 4. This *Candida* also revealed sensitivity to fluconazol. No effect on yeast growth was detected when exposed to DMSO.

![Figure 4](image.png)

**Figure 4:** Antifungal activity of different *C. citratus* EO concentrations against *Candida* spp. * statistically different (95% significance) from negative control DMSO.
Data on *C. albicans* is in accordance with other studies [48,49] but, to the best of our knowledge, this is the first reported data on EO antifungal activity on the NCAC. The fact that EO has proved effective against NCAC at all concentrations tested is the more relevant as recent epidemiologic studies report that NCAC are currently estimated to be responsible for approximately 60% of fungaemia [50]. These results put in evidence the antifungal activity of *C. citratus* EO, which should be considered in further investigations namely in order to assess the sensitivity of other NCAC.

**Conclusions**

The Angolan *C. citratus* EO was found to have greater antioxidant activity than methanolic extracts obtained from the leaves and similar to that exhibited by the synthetic antioxidant BHT. The oil however has, in this respect, an important advantage over BHT: due to their natural origin; the antioxidants obtained from plants not induce the negative side effects provoked by synthetic ones such as BHT which has proved to cause hemorrhaging. Published studies showed that the *C. citratus* EO is innocuous for mammals and lacks any kind of genotoxic or toxic effects in mice. The EO exhibited high antibacterial and anti-yeast properties including against multidrug resistant strains of *S. aureus*, *S. epidermidis*, *E. coli*, *K. pneumonia* and NCAC spp *C. parapsilosis* and *C. tropicalis*. Taking into account the results of this study the antimicrobial activity of the *C. citratus* EO against many other pathogenic or spoilage microorganisms, it can be concluded that it meets several features that make it a good candidate for the biopreservation of food.
